

# Localizing Mozilla

Version 21-Jan-2002

This is a compiled manual on how to make a translation of the Mozilla/Netscape browsers using MozillaTranslator 4.36. The basic things you need to have installed in your machine are:

- The latest version of Mozilla. <http://www.mozilla.org> . It's useful that you download a Milestone (as Mozilla 0.9.5), so is a stable build, and it's going to install you the Java Runtime Environment that you will also need for MozillaTranslator.
- MozillaTranslator 4.36. <http://www.mozillatranslator.org>. It's a program written by Henrik Lynggaard that make the translation process really easy.
- I would recommend you to have a compression program as [WinZip](#) or WinRAR.
- And for any doubt, there is a newsgroup: [mozilla.110n](mailto:mozilla.110n@netscape.com).
- The official localization project for mozilla is <http://www.mozilla.org/projects/110n/mlp.html> . Be sure to check it before you start, and contact the administrator to inform that you are going to start a new localization project.

## Installing Mozilla

- Download the latest Mozilla version from . <http://www.mozilla.org> and install it on your system. This shouldn't give you any problems.

## Starting a translation

Be sure that nobody is already localizing (translating) Mozilla to your language, because if so, the best thing would be to join that person or group and not to duplicate the effort.

- Download MozillaTranslator 4.36 from . <http://www.mozillatranslator.org> . You don't have to install this one, it's a java program that can be run from the Start-Run-select the name of this program. If you have already installed Mozilla, you have the Java Runtime Environment necessary to run this program.

1.- If you are using Windows, go to Start, Run, and select this program. Click OK to open it.

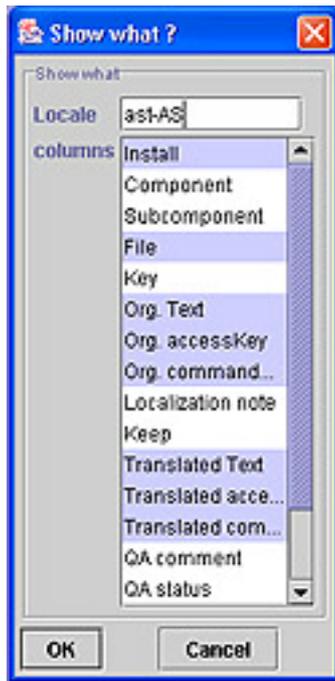

2.- Go to *File, Setup* and click "Enable Kazu's workaround for bug 51327". OK.

3.- Now you have to load the English version of Mozilla into MozillaTranslator, so you can start localizing. To do that, you have to go to *File - Manage Installs*. A new window opens. Click *Add* , and a new window opens asking you for the name and location of the install you want to do. Click in *Choose* and browse to the Mozilla chrome directory that is under *C:\Program Files\Mozilla.org\Mozilla\chrome*. There you will find different files. Click on **en-US.jar**. OK. And then you are back to the *Edit Installation* window. Now you have to provide a name for your new "locale", that usually it has the two first letters of the name of your language, a dash, and the two first letters of your country. For example: if you are going to translate Mozilla to Spanish (es) but you want to use the Spanish spoken in Argentina (AR), then the name of your locale should be something like **es-AR.jar**. NOTE: The code names are assigned by the ISO 634 authority (<http://www.loc.gov/standards/iso639-2/>), so check which is the code for your language.

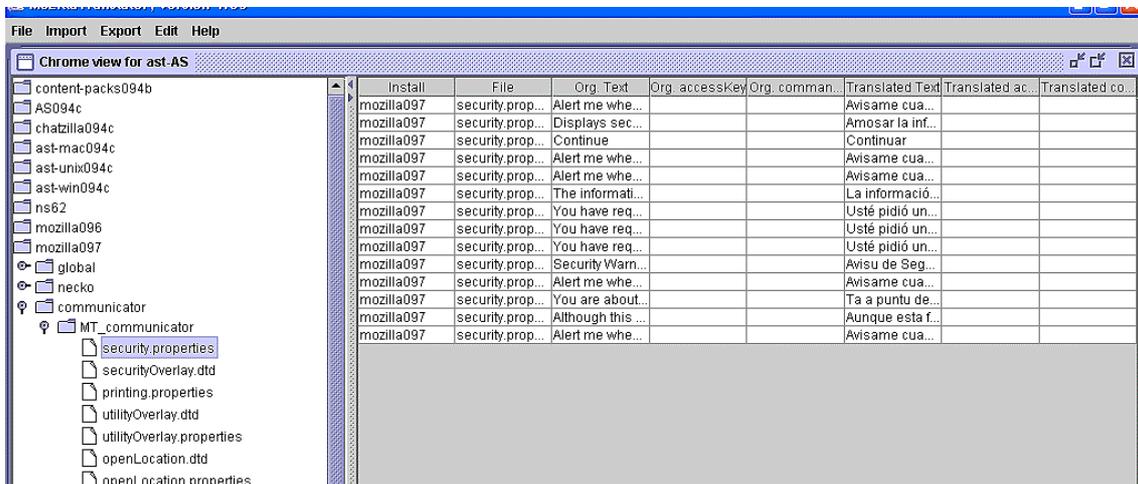

Once you have added a new language, you have to update it (*File-Update Install*). Select the *Install to update*, and click *Update*.

To start translating, MozillaTranslator offers you different possibilities. The best thing to get familiarized with MT is start with *Edit-Chrome View*.

Once you have clicked in *Edit-Chrome View*, the menu "*Show what?*" pops-up asking you what things do you want to see while translating. I like *File, Org. Text, Org. accesskey, Org. commandkey, Translated Text, Translated accesskey, and Translated commandkey*. After that click OK.

Now you should see the 7 columns you have selected, and on the left side, the components that you have. Expand the folder on your left and you'll see the different components present there. Go to anyone, i.e. *Communicator*, and inside it, you will find more subfolders, go to *MT-communicator* and click on *security.properties*. Now you will see on the right panel the strings that you have to translate. Click on the first one, under the column "Translated text", and start translating.

If the sentence to translate is very long and you cannot see it, press Alt-E, and you can easily translate long sentences.

A very convenient option is *Edit - Redundant Strings*. This option sorts all the strings that are redundant (i.e. File, so you can translate the first one, and then copy and paste for the remaining ones).

Once you have localized all or part of the strings, go to *File - Save Glossary*. You can exit MozillaTranslator from *File - Exit*. When you open again MT, you will resume at the same point you left it before.

## Writing a Language Pack

I assume you already have localized *en-US.jar* to your *ab-CD.jar* locale. So you want to export that as your locale *ab-CD.jar*. To do that, in MT you go to *Export - Write Jar*. It's going to ask you which component to export, you select your locale, and select all the components (Navigator, Messenger,...). Select which output name you want (*ab-CD.jar*) and where you want it to be saved. Click OK and will be saved.

You also need to localize three small files: *en-mac.jar*, *en-unix.jar* and *en-win.jar*. You can do that easily with MT (go to *Manage Installs*, to add those 3 installs, and *Update Install* before you can start translating them). Once you have localized them, you have to export the .jar file. Go to *Export - Write Jar*, choose *en-mac.jar* and select all its components, and name it *ab-mac.jar* (with *ab* your locale tag). Do the same for *en-unix.jar* and *en-win.jar*.

Now you should have those four files localized: *ab-CD.jar*, *ab-mac.jar*, *ab-unix.jar* and *ab-win.jar*. Put them in a folder like *C:\bin\chrome*. Download a langpack for other language (*langenus.xpi* is OK). Open *langenus.xpi* with WinZip and extract the *install.js* file to the *C:\bin* folder. Open *install.js* with Notepad and when you will find the following:

```
platformNode = getPlatform();
logComment("initInstall: platformNode=" + platformNode);
// end
// end - OS type detection
// ----LOCALIZATION NOTE: translate only these -----
var prettyName = "US English Language Pack (en-US)";
var langcode = "en";
var regcode = "US";
srDest = 500; //Required space in kB
// --- END CHANGABLE STUFF ---
var localeName = "locale/" + langcode + "-" + regcode + "/";
var langArchive = langcode + "-" + regcode + ".jar";
var platfArchive = regcode + ".jar";
```

Note the changes made: I have changed to "US English Language Pack (en-US)" you should put "Ablanguage (ab-CD) Language Pack", and "en" you should put "ab", and "US" you should put "CD".

Save it and close Notepad. Now come back to WinZip where you have the *langenus.xpi* open. Click *Add* to add the *install.js* you just modified (in options, check that you want to remember the full path). Then click *Add* to add the *ab-CD.jar*, *ab-mac.jar*, *ab-unix.jar* and *ab-win.jar*. Once you have done that, then delete the *en-US.jar*, *en-mac.jar*, *en-unix.jar*, and *en-win.jar* files from the *langenus.xpi*. Close WinZip. Now change the name of *langenus.xpi* to *langabcd.xpi*.

To test that it works, open Mozilla, click on *File - Open File*, browse to find the *langabcd.xpi* you just made. It will ask you permission to install it. Grant it. Restart

Mozilla and go to *Edit - Preferences*, in *Appearance* choose ab-CD as your language. Restart Mozilla, now should be localized.

## Leveraging

As you would know at this point, Mozilla is a developing browser, so every now and then there is a new release. Mozilla Translator allows you to export your i.e. Mozilla 0.9.5 glossary, and import it into the new Mozilla 0.9.6 glossary. To do that, download the new Mozilla version (i.e. 0.9.6) and install it (remember to unistall the previous version, read the [instructions](#)). To load the new en-US.jar into Mozilla Translator do as [before](#) (Manage Installs, Add, OK, Update Install). Take into account that you can have in MT the glossaries for as many versions as you want at the same time. So right now you'd have 2 different glossaries the abcd095 and the abcd096.

- Go to Export and Select Export Partial Glossary. Choose a folder and a name (i.e. abcdpartial095), and export the abcd095.

- To import the old translation into the new glossary, go to Import, Partial Glossay, and choose abcdpartial095, and you want to imported into abcd096.

- Now you should have all the strings you translated for the 095 glossary, into the 096 glossary. You can resume your translation and translate the new strings.

## Making an Installable Build

Once you have created a **langabCD.xpi** (and a **regCD.xpi**), and you want to create an installable build, you will need the application **mozip.exe** and the file **cygwin1.dll**. You also need the **mozilla-win32-0.9.5-installer.exe** (I'll use the 0.9.5 build as an example). **NOTE: Your langabCD.xpi language pack MUST match the version of the installer build you want to use (in this case both are 0.9.5).**

- Copy *mozip.exe*, *cygwin1.dll*, and the *mozilla-win32-0.9.5-installer.exe* to the same directory (ex: *C:\mozilla\installer*).

- From the system prompt, go to that directory (if you are not familiar with DOS, to go from C: to C:\mozilla\installer, type "cd mozilla\installer" and click return; type "dir" to see the files that are in that folder).

- The first thing you would like to do is to extract all the files present in that installer to that folder. To do that type:

"mozip -x mozilla-win32-0.9.5-installer.exe", and press enter.

- Now you can come back to Windows. There are 2 files you would like to localize in order to localize the Setup program. Those files are **CONFIG.INI** and **INSTALL.INI**. You can easily localize them with Notepad, localize only those strings under the **\*\*\* LOCALIZE ME BABY \*\*\*** marks in the CONFIG.INI file. Example:

```
[Dialog Setup Type]
Show Dialog=TRUE
;*** LOCALIZE ME BABY ***
Title=Instalación de Mozilla - Tipu d'Instalación
;*** LOCALIZE ME BABY ***
Message0=Calque nel tipu d'instalación que-y preste, darréu calque Siguiente.
Readme Filename=readme.txt
Readme App=notepad.exe
```

- In this example I've localized what is after Title=, and what is after Message0=. Shouldn't be a problem for you to do that.

- Another thing you should change in CONFIG.INI is the langpack and region pack names to install, because you want to install your ones (langabCD.xpi and regCD.xpi). To do that, check this example to see what you have to change:

```
[Component En US lang pack]
;*** LOCALIZE ME BABY ***
Description Short=Paquete de llingua Asturiana (AS)
;*** LOCALIZE ME BABY ***
Description Long=Paquete de llingua Asturiana (AS)
```

```
Archive=langastas.xpi
Install Size=768
Install Size System=1
Install Size Archive=469
Attributes=SELECTED|INVISIBLE|FORCE_UPGRADE
Force Upgrade File0=[SETUP PATH]\Chrome\ast-AS.jar
```

```
[Component US region pack]
;*** LOCALIZE ME BABY ***
Description Short=Paquete rexonal AS
;*** LOCALIZE ME BABY ***
Description Long=Conteníos rexonales pa usuarios AS
Archive=regas.xpi
Install Size=960
Install Size System=1
Install Size Archive=34
Attributes=SELECTED|INVISIBLE|FORCE_UPGRADE
Force Upgrade File0=[SETUP PATH]\Chrome\AS.jar
```

- As you can see, I have localized the strings to be localized, but I have also changed the .xpi files to be installed. Instead of *langenus.xpi* (the US English language package) I've changed it to *langastas.xpi* (the Asturian lang pack), you have to type your *langabcd.xpi*. The same for the *regus.xpi* (region pack), I've changed it to *regas.xpi*. And the last line, that specifies the US.jar file, I've changed it to AS.jar, you should change it to your cd.jar.

- Once everything is done, *copy* your *langabcd.xpi* and *regcd.xpi* to the same folder you are in (C:\mozilla\installer).

- To include those modified files (CONFIG.INI and INSTALL.INI), and your language and region packs into the installable build. Go again to the prompt, to the same folder you have mozip and all those files (C:\mozilla\installer) and type:

"mozip mozilla-win32-0.9.5-installer.exe CONFIG.INI" and press enter. Then do the same with INSTALL.INI, langabcd.xpi and regcd.xpi.

- To check that all those files are inside the installer.exe, type: "mozip -t mozilla-win32-0.9.5-installer.exe". It will display a list of files inside the installer. Check that your langabcd.xpi and regcd.xpi are there.

- Now you have a Mozilla installer for Windows. A thing I still don't know is how to remove the langenus.xpi and regus.xpi (they are around 500 kB together). To save space, a workaround is to create in the same folder (C:\mozilla\installer) a file with notepad in which you type 0, and you called langenus.xpi. So it is really small. Then you just go to the prompt and type:

"mozip mozilla-win32-0.9.5-installer.exe langenus.xpi". So it will replace the 450 kB langenus.xpi file for the 9b langenus.xpi you made.
